PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the spillway design flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. The spillway design flood provides a measure of relative spillway capacity and serves as an aid in detemining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

ASSESSMENT

The assessment of Lake Louise Dam is based upon visual observations made at the time of inspection, review of available data, and hydraulic and hydrologic analysis.

Lake Louise Dam appears to be in poor condition. Lake Louise Dam is a high hazard small size dam. The spillway design flood is in the range of 1/2 PMF to PMF. The spillway design flood was selected to be the PMF (probable maximum flood) based on downstream potential for loss of life and property damage. The spillway is capable of controlling approximately 45% of the PMF. The dam breach analysis indicated that a significant increase in the downstream potential for loss of life and property damage exists should the dam fail. Based on criteria established by the Corps of Engineers, the spillway is termed seriously inadequate. The spillway exit and entrance channels are in poor condition. The heavy vegetation creates the potential for water infiltration and made visual inspection of the embankment difficult. Lake Louise Dam is classified as an unsafe non-emergency dam.

The following recommendations and remedial measures should be instituted immediately.

1. A detailed hydrologic and hydraulic analysis should be conducted by a registered professional engineer knowledgeable in dam design and construction to increase the spillway capacity of the dam. Recommendations resulting from this study should be implemented immediately.

The spillway discharge channel and outlet is in a deteriorating condition. The outlet is being undercut by spillway discharges and subsequent cracking of the concrete channel is occurring. The spillway should be evaluated during the hydrologic and hydraulic analysis and repairs made as required. The spillway entrance is obstructed by a wire fence and trapped debris and vegetation. These obstructions should be removed immediately.

LAKE LOUISE DAM PA 558

- 2. The trees and heavy vegetation on the slopes should be removed at the direction of a registered professional engineer knowledgeable in dam design and construction. After the vegetation is removed a detailed visual inspection should be made to determine whether a stability analysis is warranted.
- 3. Erosion along the toe near the right abutment should be repaired and measures should be taken to prevent future erosion.
- 4. Some means of positive upstream closure of the drainline should be developed.
- 5. A warning system should be developed to warn any downstream residents of large spillway discharges or imminent failure of the dam.
- 6. A safety inspection program should be implemented with inspections at regular intervals by qualified personnel.

PHASE I NATIONAL DAM INSPECTION PROGRAM LAKE LOUISE DAM NDI. I.D. NO. PA 558 DER I.D. NO. 40-134

SECTION 1 PROJECT INFORMATION

1.1 General.

- a. Authority. The National Dam Inspection Act, Public Law 92-367, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a program of inspection of dams throughout the United States.
- b. Purpose. The purpose of the inspection is to determine if the dam constitutes a hazard to human life or property.

1.2 Description of Project.

- a. Dam and Appurtenances. Lake Louise Dam is an earthfill dam with a bituminous paved road and guard rails for the entire length. The dam is 16 feet high and 210 feet long. The crest width is 26 feet. The upstream slope was measured to be 1.5H: IV with heavy brush and trees. The downstream slope was measured to be 1.5H: IV with heavy brush and trees. The reservoir drain consists of a 16" cast iron pipe encased in concrete. The reservoir drain is controlled by a cast iron gate valve located at the downstream outlet of the structure. The spillway is a weir type spillway consisting of two 14 foot sections passing under a highway bridge. The exit channel is protected with dry rubble wingwalls and a concrete slab. The dam has a concrete corewall which extends from elevation 1078 to approximately 1102.
- b. Location. The dam is located on Sutton Creek, Luzerne County, Pennsylvania. Lake Louise Dam can be located on the Center Moreland, U.S.G.S. 7.5 minute quadrangle.
- c. <u>Size Classification</u>. Lake Louise Dam is a small size structure (16 feet high, 705 acre-feet).
- d. <u>Hazard Classification</u>. The hazard classification for Lake Louise Dam has been determined to be high. Downstream conditions at the time of inspection indicated that the loss of more than a few lives is probable should the structure fail. One home is located approximately 1/2 mile downstream of the dam and several homes exist within 1.5 miles downstream of the dam.

e. Ownership. Take Louise Dan is owned by Lake Louise Estates. Correspondence should be uddressed to:

Tale Louise Estates
To Olimate Equipment Company
Toolward Hill No.d
That isville, he has breaka
The 287-2129

- f. Purpose of Jan. Take Louise Dan was originally established for evention but more recently it is used for real estate detection of a
- g. Derivative construction Hillory. Construction of Take Louise Dam was a speed 1 in 1927. According to Information Hocated in P. and Time, the dam was a estructed by the Luxerae County construction Toupany, under the supervision of Fred C. Wintermute, a parassional engineer from Wilkes-Barre, Pennsylvania. No construction testing was challable for our seview, however asstruction inspection reports indicated that construction proceed I satisfactorily. There was some information in the Discribes which suggests that construction did not enform entirely to the original construction plans. However, this matter was a colved based on correspondence located in the DAR files.
- h. Normal toperating Procedures. A representative of the owner was available for interview at the time of inspection. It was determined that take Louise Estates, the present owner, obtained control of the dam in 1974. It was also determined that there are not haddled operating procedures or maintenance schemate for the control of the gate valve controlling the reservoir drain case not been opered in at least 5 years. The only maintenance that is done to the dam is provided by the state, in their efforts to be at its the roadway and the bridge.

SECTION 2 ENGINEERING DATA

- 2.1 <u>Design</u>. Correspondence and permit information was available for review in the PennDER files. Some construction drawings were also available but these drawings did appear to indicate as-built conditions. No additional information was provided by the owner.
- 2.2 Construction. Some information was available in the PennDER files on the construction of the dam. One inspection report prepared by Fred C. Wintermute stated that construction was progressing satisfactorily. One correspondence report between Mr. Wintermute and the Department of Forest and Waters, explains that as-built conditions do not represent the design. The as-built conditions were presented to the Department of Forest and Waters and approved by them. These drawings do not exist in the current DER file.
- 2.3 Operation. No operating records are known to exist. The state maintains the bridge and roadway over the dam.

2.4 Evaluation.

- a. Availability. Engineering data were provided by PennDER, Bureau of Dams and Waterways Management. A representative of the owner provided information on recent history and maintenance of the structure during the inspection.
- b. Adequacy. Minimal design data was available for review for the purpose of this report. Limited information was available for review concerning the construction of the dam. No as-built drawings exist in the DER files. This Phase I Report is based on available data, visual inspection, hydrologic and hydraulic analysis. Sufficient information exists to complete a Phase I Report.

SECTION 3 VISUAL INSPECTION

3.1 Findings.

- a. General. The on site inspection of Lake Louise Dam was conducted by personnel of L. Robert Kimball and Associates on May 21, 1980 and July 30, 1980. The inspection consisted of:
 - 1. Visual inspection of the retaining structure, abutments and toe.
 - Examination of the spillway facilities, exposed portion of any outlet works and other appurtenant works.
 - 3. Observations affecting the runoff potential of the drainage basin.
 - 4. Evaluation of the downstream area hazard potential.
- b. Dam. The dam appears to be in poor condition. From a brief survey conducted during the inspection, it was noted that the main embankment crest has a low spot midway across the embankment. The crest of the embankment is a paved state maintained roadway. The upstream and downstream slopes are covered with heavy brush and trees. At least one large tree had fallen creating a depression, slope over steepening and a location for infiltration and potential stability problems. No seepage was noted on the embankment or at the toe, however several wet spots exist beyond the toe. Erosion was noted along the right abutment contact resulting from roadway drainage.

An active slide, in natural ground, is present on the left abutment near the spillway exit channel. This slide has moved soil material into the exit channel and several large trees have fallen into the exit channel.

c. Appurtenant Structures. The waterlevel at the time of the inspections was estimated to be at elevation 1093.0. The spillway approach and exit channels are in poor condition. The spillway entrance channel is blocked by vegetation debris and a deteriorating fence (fish screen) across the spillway catches debris and increases blockage. The concrete exit channel is extensively cracked due to undercutting at the toe of the concrete. If this condition is allowed to continue it could lead to possible deterioration in the entire exit channel and could cause stability problems of the wingwalls and ultimate spillway failure. The wingwalls consist of masonry rubble and currently show movement and separation. The drainline for the reservoir consists of a 16" cast iron pipe encased in concrete. The drain is controlled by a 16" gate valve which has not been operated in at least 5 years. The overall condition of the

drainline is unknown. The intake and discharge structures were unobserved during the inspection. The valve chamber at the toe of the dam was observed during the inspection. No upstream shutoff is provided in the drainline.

- d. Reservoir Area. The watershed is covered mostly with timber. The reservoir slopes are gentle to moderate and do not appear to be susceptible to massive landslides which would affect the storage volume of the reservoir or cause overtopping of the dam by displacing water.
- e. <u>Downstream Channel</u>. The downstream channel of Lake Louise Dam is Sutton Creek a relatively narrow creek. The dam is about four miles from the North Branch of the Susquehanna River.
- 3.2 Evaluation. In general, the embankment, spillway structure and outlet works appear in poor condition.

SECTION 4 OPERATIONAL PROCEDURES

- 4.1 <u>Procedures</u>. The water level is maintained at the spillway crest elevation of 1093.0. A representative of the owner indicated that there is no maintenance schedule or operational procedures.
- 4.2 <u>Maintenance of the Dam</u>. No planned maintenance schedule for the dam exists other than the maintenance of the roadway by state maintenance crews.
- 4.3 <u>Maintenance of Operating Facilities</u>. Operating facilities for the dam have not been maintained or operated in at least 5 years. The condition of these facilities are unknown.
- 4.4 Warning System in Effect. There is no known warning system in effect to warn downstream residents or property owners of large spillway discharges or imminent failure of the dam. At the time of inspection there were several downstream residences.
- 4.5 Evaluation. The condition of the operating facilities is unknown and no maintenance procedures exists. There is no warning system to warn downstream residents.

SECTION 5 HYDRAULICS AND HYDROLOGY

5.1 Evaluation of Features.

- a. Design Data. The PennDER files contained only minimal hydrologic and hydraulic design information. There are some hand written calculations in the files, however these do not seem to be part of the design criteria. Information in the files suggested that the spillway design dealt with bridge stability rather than hydrologic or hydraulic considerations.
- b. Experience Data. No rainfall or runoff data were available. It was indicated that the maximum known reservoir level obtained was 6" above the normal pool level. The spillway reportedly has functioned adequately in the past.
- c. <u>Visual Observations</u>. The spillway approach and discharge channels are in poor condition. The upstream channel is blocked by vegetation and debris while the downstream channel has extensive deterioration due to undercutting of concrete at the toe. A fence (fish screen) across the spillway crest traps debris and will cause further blockage.
- d. Overtopping Potential. Overtopping potential was investigated through the development of the probable maximum flood (PMF) for the watershed and the subsequent routing of the PMF and fractions of the PMF through the reservoir and spillway.

The Corps of Engineers, Baltimore District, has directed that the HEC-1 Dam Safety Version systemized computer program be utilized. The program was prepared by the Hydrologic Engineering Center (HEC), U.S. Army Corps of Engineers, Davis, California, July, 1978. The major methodologies or key input data for this program are discussed briefly in Appendix D.

- 5.2 <u>Evaluation Assumptions</u>. To enable us to complete the hydraulic and hydrologic analysis for this structure, it was necessary to make the following assumptions.
- 1. Pool elevation prior to the storm was at the spillway crest elevation of 1093.0.
- 2. Cummings Pond a natural upstream pond exists and was considered capable of storing some of the inflow. Lake Manjo a small man made upstream pond was ignored in this analysis.
- 3. Top of the dam was considered to be at the low spot elevation of 1101.0 feet.

- 4. Blockage of the spillway was not taken into account.
- 5.3 Summary of Overtopping Analysis. Complete summary sheets for the computer output are presented in Appendix D.

Peak inflow (PMF) Spillway capacity

7340 cfs 2039 cfs

a. Spillway Adequacy Rating. The Spillway Design Flood (SDF) for a dam of this size and classification is in the range of 1/2 PMF to PMF. The SDF is based on the hazard and size classification of the dam. Based on the hazard potential for this dam the spillway design flood (SDF) was selected to be the PMF. Based on the following definition provided by the Corps of Engineers, the spillway is rated as seriously inadequate as a result of our hydrologic analysis.

Seriously inadequate - High hazard classification dams not capable of passing 50% of the spillway design flood and where there is a significant increase in the downstream hazard potential for loss of life due to overtopping failure.

The spillway and reservoir are capable of controlling approximately 45% of the PMF without overtopping the embankment at the low spot. Because of the blockage of the spillway entrance the spillway capacity could be further reduced.

5.4 <u>Summary of Dam Breach Analysis</u>. The subject dam cannot satisfactorily pass 50% of the PMF based on our analysis therefore it was necessary to perform the dam breach analysis and downstream routing of the flood wave. This analysis determined the degree of increased flooding due to dam failure.

The 1/2 PMF storm overtops the low spot on the dam crest by 1.10 feet for a duration of 2.25 hours. A reservoir pool elevation of 1102 was considered sufficient to cause failure of the Lake Louise Dam. This elevation represents a depth of overtopping of approximately 1 foot over the low spot of the dam and approximately 1.3 inches over the critical left abutment area.

The resulting flood wave was routed downstream with and without failure considerations. Downstream potential for loss of life and property damage is significantly increased by dam failure. Therefore the spillway is rated as seriously inadequate. A detailed printout of the breach analysis is included in Appendix D.

SECTION 6 STRUCTURAL STABILITY

6.1 Evaluation of Structural Stability.

a. <u>Visual Observations</u>. Visual observations indicated a slide in natural ground near the left abutment and erosion along the downstream toe near the right abutment. The spillway wingwalls which consist on masonry rubble slow signs of deterioration.

The stability of the dam is of concern because of the fairly steep slopes and the dense vegetation. At least one large tree has fallen creating the potential for water infiltration and potential stability problems. There is no indication that a stability analysis had been performed in the past. The vegetation on the slope should be removed in a controlled manner. After removal, a detailed visual inspection should be conducted by a registered professional engineer knowledgeable in dam design and construction to determine whether a stability analysis of the structure should be conducted.

- b. <u>Design and Construction Data</u>. No stability analysis was conducted for this dam. No as-built drawings were available for review by the inspection team and limited construction data is available.
 - c. Operating Records. No operating records are maintained.
- d. <u>Post Construction Changes</u>. There were no indications of any post construction changes in the DER files. There were no as-built drawings available for review.
- e. Seismic Stability. The dam is located in seismic zone l. No seismic stability analysis has been performed. Normally, it can be considered that if a dam in this zone is stable under static loading conditions, it can be assumed safe for any expected earthquake loading. No visual deficiences were observed during the inspection. There exist no known stability analysis to document the stability of the dam.

SECTION 7 ASSESSMENT AND RECOMMENDATIONS/REMEDIAL MEASURES

7.1 Dam Assessment.

a. <u>Safety</u>. Lake Louise Dam was heavily vegetated making the inspection difficult. The dam appeared to be in poor condition. A small slide was observed near the left abutment in natural ground adjacent to the spillway wingwall. Erosion was observed along the downstream toe of the embankment. Both slopes are covered with heavy brush and trees and at least one large tree had fallen. Falling trees could lead to infiltration and could cause potential instability.

Visual observations, and hydrologic and hydraulic calculations indicated that Lake Louise Dam's spillway is seriously inadequate. The spillway is capable of controlling approximately 45% of the PMF without overtopping the embankment at the low spot. The dam breach analysis indicated that a significant increase in the downstream potential for loss of life and property damage exists should the dam fail. Lake Louise Dam is classified as an unsafe non-emergency dam.

- b. Adequacy of Information. This Phase I Report is based on visual observations, hydrologic and hydraulic calculations and interviews with the owners. Inspection and evaluation of the embankment was difficult due to trees and brush located on the slopes and toe.
- c. Urgency. The recommendations suggested below should be implemented immediately.
- d. Necessity for Further Investigation. In order to accomplish some of the recommendations/remedial measures outlined below, further investigations will be required. Inspection of the dam was difficult due to the heavy vegetation. A more in-depth evaluation should be made once the vegetation is removed.

7.2 Recommendations/Remedial Measures.

l. A detailed hydrologic and hydraulic analysis should be conducted by a registered professional engineer knowledgeable in dam design and construction to increase the spillway capacity of the dam. Recommendations resulting from this study should be implemented immediately.

The spillway discharge channel and outlet is in a deteriorating condition. The outlet is being undercut by spillway discharges and subsequent cracking of the concrete channel is occurring. The spillway should be evaluated during the hydrolo-

gic and hydraulic analysis and repairs made as required. The spillway entrance is obstructed by a wire fence and trapped debris and vegetation. These obstructions should be removed immediately.

- 2. The trees and heavy vegetation on the slopes should be removed at the direction of a registered professional engineer knowledgeable in dam design and construction. After the vegetation is removed a detailed visual inspection should be made to determine whether a stability analysis is warranted.
- 3. Erosion along the toe near the right abutment should be repaired and measures should be taken to prevent future erosion.
- 4. Some means of positive upstream closure of the drainline should be developed.
- 5. A warning system should be developed to warn any downstream residents of large spillway discharges or imminent failure of the dam.
- 6. A safety inspection program should be implemented with inspections at regular intervals by qualified personnel.

APPENDIX D HYDROLOGY AND HYDRAULICS

Methodology. The dam overtopping and breach analyses were accomplished using the systemized computer program HEC-1 (Dam Safety Investigation), September, 1978, prepared by the Hydrologic Engineering Center, U.S. Army Corps of Engineers, Davis, California. A brief description of the methodology used in the analysis is presented below.

l. Precipitation. The Probable Maximum Precipitation (PMP) is derived and determined from regional charts prepared from past rainfall records including "Hydrometeorological Report No. 40" prepared by the U.S. Weather Bureau.

The index rainfall is reduced from 10% to 20% depending on watershed size by utilization of what is termed the HOP Brook adjustment factor. Distribution of the total rainfall is made by the computer program using distribution methods developed by the Corps.

2. <u>Inflow Hydrograph</u>. The hydrologic analysis used in development of the overtopping potential is based on applying a hypothetical storm to a unit hydrograph to obtain the inflow hydrograph for reservoir routing.

The unit hydrograph is developed using the Snyder method. This method requires calculation of several key parameters. The following list gives these parameters their definition and how they were obtained for these analysis.

Parameter	Definition	Where Obtained
Ct	Coefficient representing variations of watershed	From Corps of Engineers*
L	Length of main stream channel miles	From U.S.G.S. 7.5 minute topgraphic
Lca	Length on main stream to centroid of watershed	From U.S.G.S. 7.5 minute topographic
Ср	Peaking coefficient	From Corps of Engineers*
A	Watershed size	From U.S.G.S. 7.5 minute topographic

*Developed by the Corps of Engineers on a regional basis for Pennsylvania.

3. Routing. Reservoir routing is accomplished by using Modified Plus routing techniques where the flood hydrograph is routed through reservoir storage. Hydraulic capacities of the outlet works, spillways and the crest of the dam are used as outlet controls in the routing.

The hydraulic capacity of the outlet works can either be calculated and input or sufficient dimensions input and the program will calculate an elevation discharge relationship.

Storage in the pool area is defined by an area - elevation relationship from which the computer calculates storage. Surface areas are either planimetered from available mapping or U.S.G.S. 7.5 minute series topographic maps or taken from reasonably accurate design data.

- 4. Dam Overtopping. Using given percentages of the PMF the computer program will calculate the percentage of the PMF which can be controlled by the reservoir and spillway without the dam overtopping.
- 5. Dam Breach and Downstream Routing. The computer program is equipped to determine the increase in downstream flooding due to failure of the dam caused by overtopping. This is accomplished by routing both the pre-failure peak flow and the peak flow through the breach (calculated by the computer with given input assumptions) at a given point in time and determining the water depth in the downstream channel. Channel cross-sections taken from U.S.G.S. 7.5 minute topographic maps were used in the downstream flood wave routing. Pre and post failure water depths are calculated at locations where cross-sections are input.

HYDROLOGY AND HYDRAULICS ANALYSIS DATA BASE

APPENDIX F GEOLOGY

General geology

Lake Louise and its dam lie within the (Glaciated) Low Plateaus Section of the Appalachian Plateaus Physiographic Province. This area is characterized by broad anticlines and synclines and little, if any, faulting. There are no known faults in the vicinity of the dam.

The rocks underlying the lake and dam consist of the Devonian aged Susquehanna Group. This is a complex unit of conglomerate, sandstone, siltstone and shale. The usually well developed bedding ranges in thickness from less than one to over fifteen feet. The well developed joints are regular and closely spaced in the shales and siltstones. They are vertical or steeply dipping and usually form a blocky or platy pattern. The shales disintegrate rapidly, but the siltstone, sandstone and conglomerate are fairly resistant to weathering. The rocks of the Susquehanna Group form a good foundation for heavy structures if excavated to sound material and the shales and siltstones are kept water free. The interstitial porosity of the coarser rocks is low, but joint development has created a medium level effective porosity.

GEOLOGIC MAP OF THE AREA AROUND LAKE CATALPA DAM AND LAKE LOUISE DAM

Oswayo Formation

Oswayo r oremation. Brownish and greenish grap, fine and medium grained anadetones with some sheles and scattered calcarenus lense; includes red sheles which become more numerous castward. Relation to type Quego not proced.

Catakill Formation
Chiefly red to brownish shales and sandstones; includes gray and greenish sandstones tongues named Elk Mountain,
Honosdels, Shohole, and Dolowers River
in the east.

Marine heds
Gray to dive brown shales, graywackes, and sandstones; contains "Chemung" beds and "Portage" beds including Burket, Brallier, Harrell, and Trimmers Rock; Tully Limestone at base.

SCALE 1:250,000

Susquehanna Group

Parted line is "Chemung-Catchill" con-tuet of Second Pennsylvania Survey County reports; barbs on "Chemung" side of line.
